BACKGROUND Blood transfusion is used to treat several life threatening diseases including acute anemia. Every day in many low resources countries, women are frequently dying during childbirth due to the lack of blood availability in transfusion centers. Moreover, these countries can experience significant problems with the transmission of infectious diseases through the use of blood infected by bacteria, viruses and parasites.

Our project, supported by the Humanitarian Foundation of the Swiss Red Cross, aims at finding a solution to improve the safety of transfusion practice in Africa. It entails the adaptation of Cerus' INTERCEPT Blood System for red blood cells (RBCs) for pathogen inactivation (PI) of whole blood (WB) and is specifically being developed for sub-Saharan African countries where infrastructures and resources are lacking.

AIM The first step of this project was to determine the effects of pathogen inactivation on different RBC parameters in treated whole blood.

MATERIALS AND METHODS WB units were treated with S-303, an alkylating agent used to crosslink nucleic acids and prevent replication of contaminating pathogens, and glutathione (GSH) used to quench non-specific reactions with proteins. The concentrations used for the treatment were 0.2 mM of S-303 and 2, 5, 10 and 20mM of GSH. The blood units were stored at room temperature during the experiment and were tested at different time points after treatment (24h, 48h, 72h and 7 days) for the following parameters: hematocrit, osmotic fragility, ATP, pH, lactate, K+ and the percentage of hemolysis.

- **Hematocrit (HTC)** is the relative percentage of the volume of cells circulating in blood reported to the total volume of blood. It gives an indication of the volume occupied by the RBCs. Hematocrit was obtained using a Sysmex KX-21.
- **Osmotic fragility** was determined by the measure of hemoglobin released from RBCs, when placed in an environment containing serial dilutions of Phosphate Buffered Saline (PBS).
- The percentage of hemolysis was calculated using the mathematical formula:

$$\% \text{ Hemolysis} = \frac{\text{free Hb} \times (100 - \text{HTC})}{\text{Hb Sysmex}}$$

RESULTS

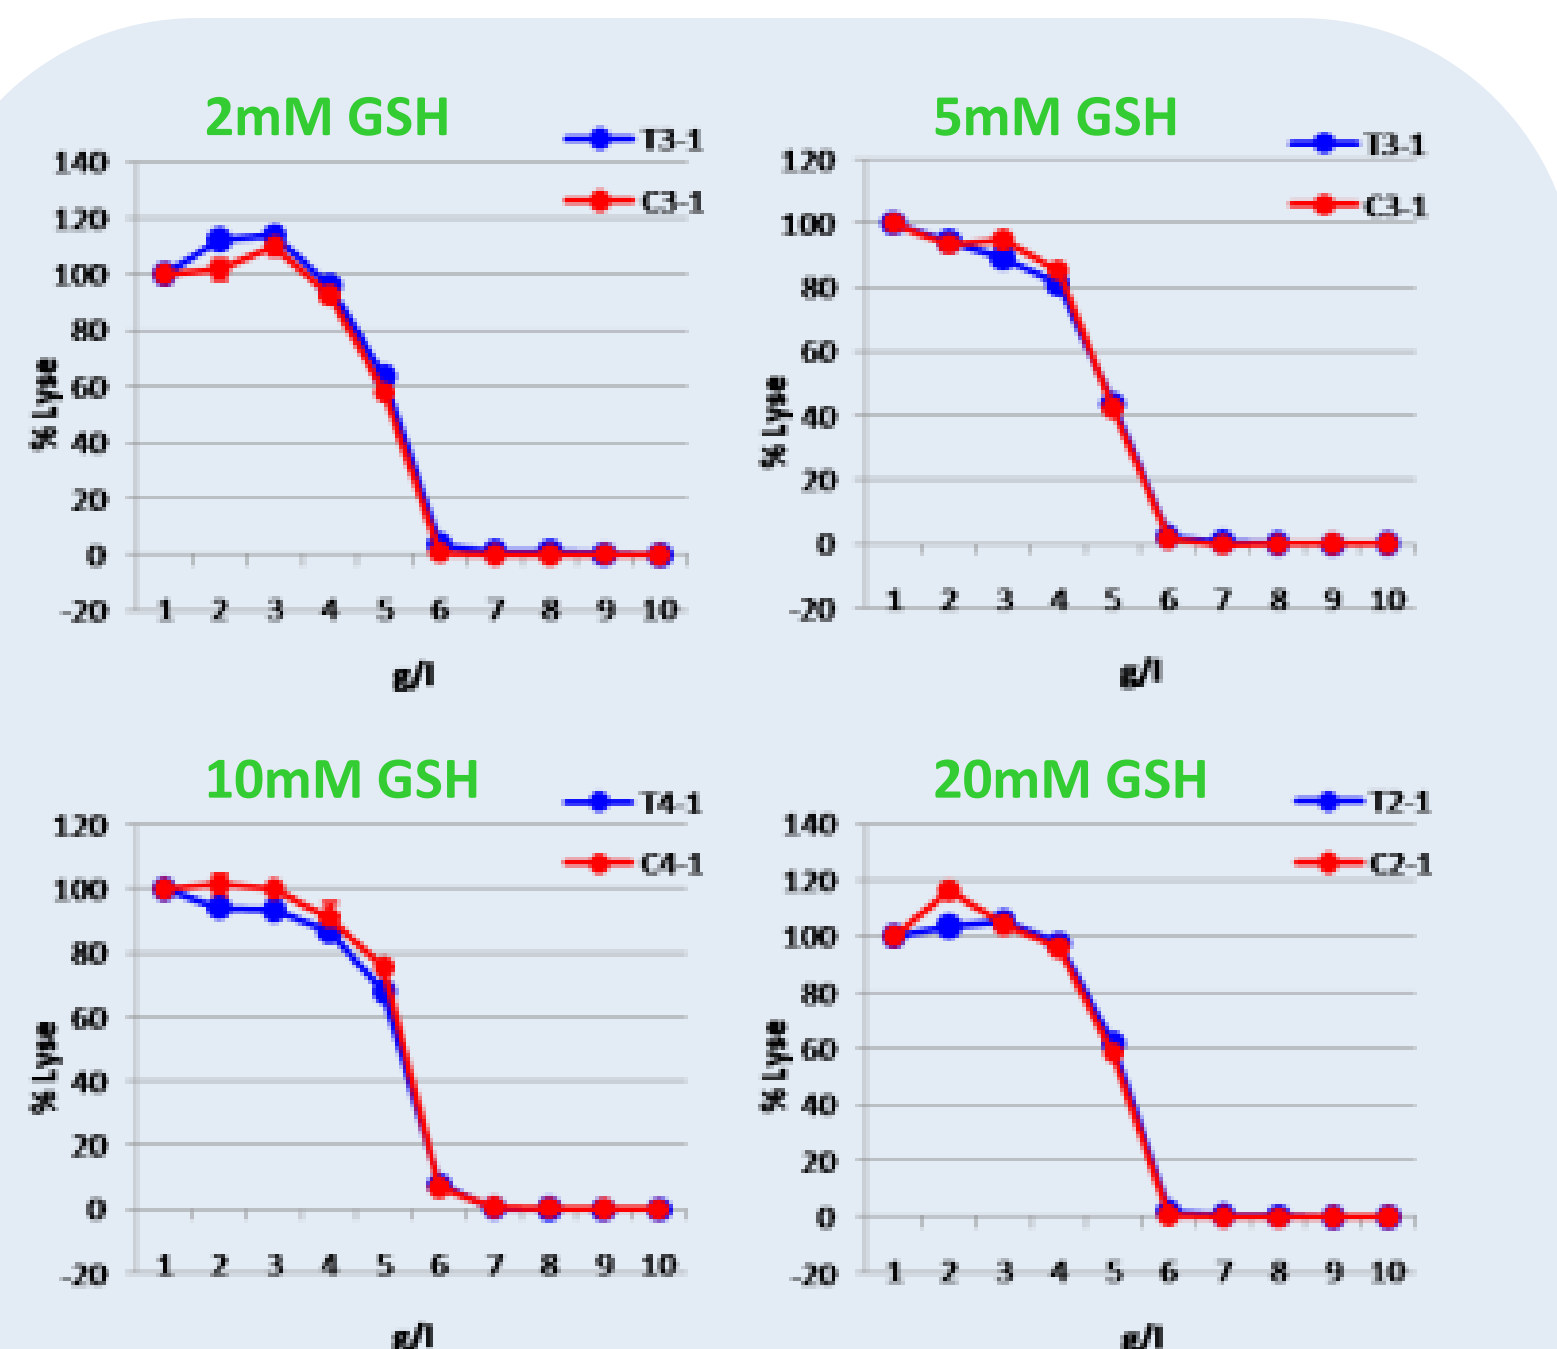

FIGURE 1: OSMOTIC FRAGILITY

- The more RBCs are stressed, the more the curves are left shifted (Blasi et al., Transfusion Medicine, 2014)

- Perfect overlapping of C and T curves
- No effect of treatment on osmotic fragility

FIGURE 2: HEMATOCIT AND % OF HEMOLYSIS

• A rise in free hemoglobin indicates hemolysis.

In blood RBC units, hemolysis has to be < 0.8% → our results are in the accepted range, according to the EDQM blood transfusion guides.

• HTC % and total hemoglobin concentration are stable with time, and slightly higher in control samples than in treated samples.

FIGURE 5: pH

- The pH decreased over time likely due to the increase of lactate with time.
- pH slightly lower in T compared to C; may be due to acidic S-303 molecule

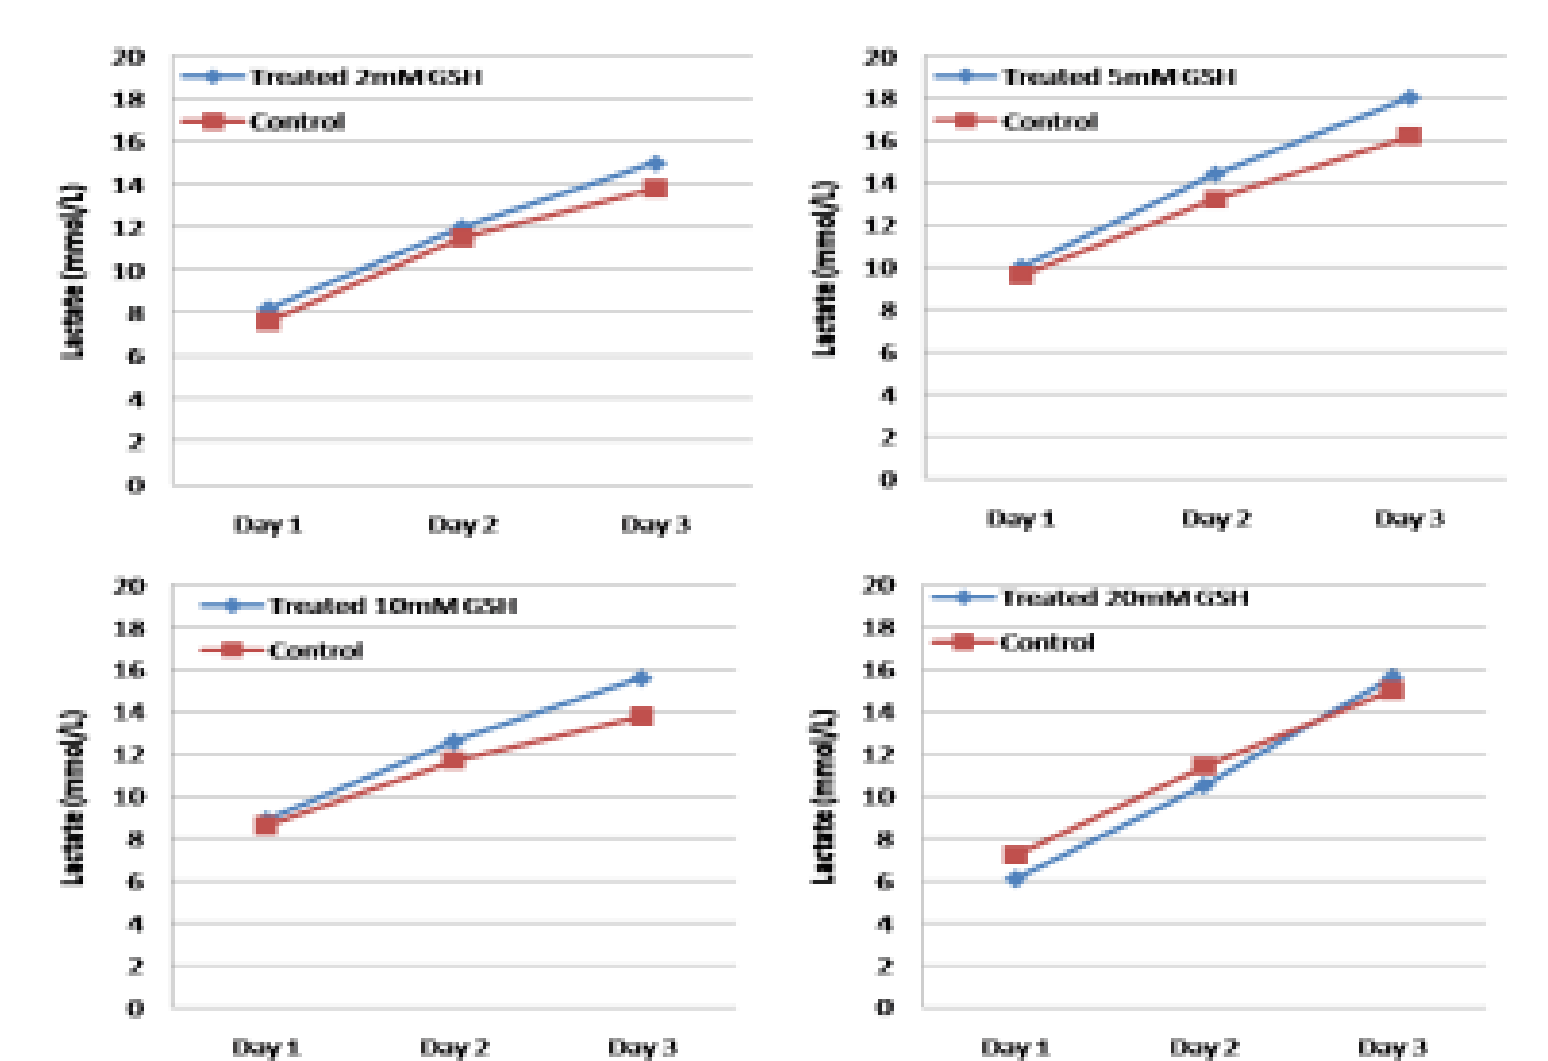

FIGURE 6: LACTATE

- Lactate production increases with time.
- Lactate levels in T samples are slightly higher than in C samples

CONCLUSIONS Although the sample size was small, interestingly the experiments showed acceptable results in treated and control WB units for most of the tested parameters, indicating that RBC viability and function are preserved after treatment. These preliminary results for S-303-treated whole blood are very encouraging, suggesting that pathogen inactivated whole blood could represent a safe and innovative blood product for transfusion. The next step will consist of in-depth studies of the treatment's effects, in particular on coagulation factors and platelet functions.
